The Let Statement & Basic Pattern Matching

- Up till now we have used the let statement basically as an assignment statement into a single variable in the imperative fashion

  let <var> = <value>.

```
load system io.

let a = [1,2,3].      -- construct list a
let b = a@[2,1,0].    -- reverse list a using slice [2,1,0]
io @println b.
```

The Let Statement & Basic Pattern Matching

- However, the let statement is a pattern-match statement in Asteroid,
```
let <pattern> = <value>.
```

- where the pattern on the left side of the equal sign is matched against the value of the right side of the equal sign.
- **Simple patterns are expressions that consist purely of constructors and variables**

The Let Statement & Basic Pattern Matching

- When the pattern is just a single variable then the let statement looks like an assignment statement,

```
let x = 1.
```

Pattern → ← Value

- However, statements like,

```
let 1 = 1.
```

- are completely legal,
  - the 1 on the left is a constructor viewed as pattern, the 1 on the right is a constructor viewed as a value.
 - highlighting the fact that the let statement is not equivalent to an assignment statement.

Pattern Matching – Foundations

- In programs values are represented by **constructors**,
  - 1
  - "Hello, World!"
  - [1,2,3]
  - ("Harry", 32)
- Any structure that cannot be reduced any further consists purely of constructors and is the **minimal/canonical representation** of a value.
- The following are all representations of the value two:
  - 1+1; 3-1; 2*1; 2+0; 2
  - Only the last one is the canonical representation of the value two.
  - We say that 2 is a constructor for the value two.
  - In this case the constructor happens to be a constant.

Pattern Matching – Foundations

- Here is another example using lists
- The following are all representations of a list with the values one, two, and three
  - [1]+[2]+[3]; [1,2]+[3]; [1,2,3]+[]; [1,2,3]
- Again, only the last one is the canonical representation of the list
Pattern Matching – Foundations

- Patterns are all about structure
- For example,
  - a wildlife biologist might use pattern matching to identify a specific species of bird based on its size, coloration, and distinctive markings on its feathers – **structure**.
  - They would compare these characteristics to a known set of **patterns** for different bird species from a field guide and use this information to make an accurate identification.
- Observe, the structure of a value (unknown bird) is pattern-matched against a set of known patterns. If one of the patterns matches the value (bird) then we have a match (identification).

Pattern Matching – Foundations

- We can code that biologist example in Asteroid

- Assume we have a field guide with the following patterns
  - Bird("big","blue","yellow dots") → "blue polka"
  - Bird("tiny","red","green stripes") → "green striped finch"
  - Bird("tiny","red","black stripes") → "striped sparrow"
  - And we observed a bird
    - Bird("tiny","red","black stripes")
  - Identify the observed bird.

```
1    load system io.
2
3    structure Bird with
4       data size.
5       data coloration.
6       data markings.
7    end
8
9    let observed_bird = Bird("tiny","red","black stripes").
10
11   try
12      let Bird("big","blue","yellow dots") = observed_bird. -- pattern match
13      io @println "it is a blue polka".
14   catch Exception(_,error) do
15      io @println error.
16   end
17
18   try
19      let Bird("tiny","red","green stripes") = observed_bird.  -- pattern match
20      io @println "it is a green striped finch".
21   catch Exception(_,error) do
22      io @println error.
23   end
24
25   try
26      let Bird("tiny","red","black stripes") = observed_bird.  -- pattern match
27      io @println "it is a striped sparrow".
28   catch Exception(_,error) do
29      io @println error.
30   end
```

ln004/bird1.ast

```
[lutz$ asteroid bird1.ast
pattern match failed: regular expression 'big' did not match 'tiny'
pattern match failed: regular expression 'green stripes' did not match 'black stripes'
it is a striped sparrow
lutz$ 
```

Pattern Matching – Foundations

- Variables allow for partial matches
- Variables in patterns are instantiated in the current environment

```
1    load system io.
2
3    structure Bird with
4       data size.
5       data coloration.
6       data markings.
7    end
8
9    let observed_bird = Bird("tiny","red","black stripes").
10   let Bird("tiny","red",m) = observed_bird.  -- pattern match
11
12   -- variables in patterns are instantiated
13   assert (isdefined "m").
14   assert (m == "black stripes").
```
ln004/bird1.ast

Basic Patterns

- Something a bit more CS related

```
[lutz$ asteroid
Asteroid Version 1.1.4
(c) University of Rhode Island
Type "asteroid -h" for help
Press CTRL-D to exit
[ast> let 1 = 1.
[ast> let 2 = 1 + 1.
[ast> let 1+1 = 2.
error: pattern match failed: term and pattern disagree on struct
[ast> let 1+1 = 1+1.
error: pattern match failed: term and pattern disagree on struct
ast>
```

```
[lutz$ asteroid
Asteroid Version 1.1.4
(c) University of Rhode Island
Type "asteroid -h" for help
Press CTRL-D to exit
[ast> let x = 1.
[ast> x
1
[ast> let (x,2) = (1,2).
[ast> x
1
ast>
```

```
[lutz$ asteroid
Asteroid Version 1.1.4
(c) University of Rhode Island
Type "asteroid -h" for help
Press CTRL-D to exit
[ast> let [x,2,y] = [1]+[2]+[3].
[ast> x
1
[ast> y
3
ast>
```

Basic Patterns

```
[lutz$ asteroid
Asteroid Version 1.1.4
(c) University of Rhode Island
Type "asteroid -h" for help
Press CTRL-D to exit
[ast> structure A with
[....    data a.
[....    data b.
[.... end
[ast> let o = A(1,2). -- construct object
[ast> let A(1,2) = o.
[ast> let A(x,y) = o.
[ast> x
1
[ast> y
2
ast>
```

- This also works for user defined structures/objects
- The expression A(1,2) on the left side is considered a constructor and also a pattern
- We can insert variables into the constructor, A(x,y), for easy access to the components of the object o
  - **destructuring**
Destructuring

- The idea of destructuring is fundamental to pattern matching
- It makes access to substructures much more readable (and efficient).
Without structural pattern matching

```
let p = (1,2).    -- create a structure
let x = p@0.      -- access first component
let y = p@1.      -- access second component
assert (x==1 and y==2).
```

ln004/destruct1.ast

With structural pattern matching

ln004/destruct2.ast

```
let p = (1,2).    -- create a structure
let (x,y) = p.    -- structural pattern matching, access to components
assert (x==1 and y==2).
```

Destructuring

- Here is another example using structures and objects

```
structure Person with
    data name.
    data age.
    data profession.
end

let joe = Person("Joe", 32, "Cook").   -- construct an object
let Person(n,a,p) = joe.               -- pattern match object

assert (n=="Joe" and a==32 and p=="Cook").
```

Basic Pattern Matching Summary

- The let statement
  let \<pattern\> = value .
- On the right side of equal sign constructors represent values
  - Operators/functions are allowed
- On the left side constructors represent structure
  - Operators/functions are **not** allowed
  - Constructors must minimally represent structure
- Variables are allowed in patterns for partial matches/destructuring
- Pattern matching is part of a programming paradigm called **declarative programming**
  - We will look at this more carefully when we examine control structures in Asteroid.

Pattern Matching in Python

○ Limited pattern matching available with the assignment statement

  ● Called **destructuring** assignment

```
>>> (x,y) = (1,2)
>>> x
1
>>> y
2
>>> [a,b,c] = [1,2,3]
>>> a
1
>>> b
2
>>> c
3
>>>
```

Pattern Matching in Python

- The match statement as of 3.10 provides a bit more functionality

```
>>> o = (1,2)
>>> match o:
...     case (1,2):
...         print("matched")
...     case _:
...         raise ValueError("not matched")
...
matched
>>>
```
ln004/destruct3.py

```python
class Person:
    def __init__(self, name, age, profession):
        self.name = name
        self.age = age
        self.profession = profession

joe = Person("Joe", 32, "Cook")

match joe:
    case Person(name=n,age=a,profession=p):
        pass
    case _:
        raise ValueError("match error")

assert (n=="Joe" and a==32 and p=="Cook")
```

https://peps.python.org/pep-0636/

# Pattern Matching in Rust

- Rust also supports pattern matching

ln004/destruct2.prs

```
fn main () {
    let p = (1,2);
    let (x,y) = p;
    assert!(x==1 && y==2);
}
```

ln004/destruct3.rs

```
struct Person {
    name: String,
    age: u8,
    profession: String,
}

fn main() {
    let joe = Person {
        name: "Joe".to_string(),
        age: 32,
        profession: "Cook".to_string()
    };

    let Person { name:n, age:a, profession:p } = joe;

    assert!(n == "Joe" && a == 32 && p == "Cook");
}
```
Conditional Pattern Matching

```
ast> let (x,y) if x==y = (1,1).
ast> let (x,y) if x==y = (1,2).
error: pattern match failed: conditional pattern match failed
ast>
```

```
ast> let x if x >= 0 = 1.
ast> let x if x >= 0 = -11.
error: pattern match failed: conditional pattern match failed
ast>
```

- Only assign a pair if the two component values are the same
- Only assign positive values to x

The is Predicate

- The is predicate is of the form
    <value> is <pattern>
  and returns true if the value matches the pattern otherwise it will return false

- The is predicate allows us to do pattern matching is expressions

```
[ast> [1,2] is [x,2].
true
[ast> x
1
ast>
```

Type Patterns

- Type patterns are patterns of the form
  %<type name>
  and match all instances of the <type name>
- All built-in types have associated type patterns such as %integer, %real, %string etc.
- User defined types are also supported,
  %<user defined type name>

```
[ast> let %integer = 1.
[ast> let %integer = 1.0.
error: pattern match failed: expected type 'integer' got a term of type 'real'
ast>
```

```
[ast> struct MyType with
error: expected 'EOF' found 'with'.
[ast> structure MyType with
[....     data a.
[....     data b.
[.... end
[ast> let %MyType = MyType(1,2).
[ast> let %MyType = 3.
error: pattern match failed: expected type 'MyType' got an object of type 'integer'
ast>
```

Advanced Pattern Match Expressions

- We can combine conditional pattern matching with type patterns and the is predicate to express sophisticated patterns
- E.g., only assign a value to x if it is an integer value

```
[ast> let x if x is %integer = 1.
[ast> x
 1
[ast> let x if x is %integer = 1.0.
 error: pattern match failed: conditional pattern match failed
ast>
```

Advanced Pattern Match Expressions

○ Here are some additional examples,

```
[ast> let x if (x is %real) and (x > 0.0) = 3.14.
[ast> x
 3.14
```

```
ast> load system math.
ast> let x if (x is %integer) and not math @mod (x,2) = 4.
ast> x
4
ast> let x if (x is %integer) and not math @mod (x,2) = 5.
error: pattern match failed: conditional pattern match failed
ast> let x if (x is %integer) and not math @mod (x,2) = 4.0.
error: pattern match failed: conditional pattern match failed
ast>
```
Note: 'mod' is the modulus function

Named Patterns

- The simple conditional pattern
  x if x is \<pattern\>
  appears a lot in Asteroid programs
- Named patterns of the form
  x:\<pattern\>
  represent a shorthand for the simple conditional pattern above
- E.g.

```
[ast> let p if p is (x,y) = (1,2).
[ast> p
(1,2)
[ast> let p:(x,y) = (1,2).
[ast> p
(1,2)
ast>
```

Named Patterns

○ This shorthand notation is especially useful when combined with type patterns,

```
ast> let y if y is %integer = 1.
ast> y
1
ast> let y:%integer = 1.
ast> y
1
ast> 
```

Named Patterns

- Beware: even though named patterns with type patterns look like a declarations they are not!
- They are pattern match statements; consequently, implicit type conversions we are used to from other programming languages do not work!

```
ast> let x:%real = 1.
error: pattern match failed: expected type 'real' got a term of type 'integer'
ast> let x:%real = 1.0.
ast> x
1.0
ast>
```

Head-Tail Pattern

- The head-tail pattern
     [<head var> | <tail var>]
  is a useful pattern that allows us to destructure a list into into its first element and the rest of the list; the list with its first element removed.

- As we will see later, this pattern will prove extremely useful when dealing with recursion or iteration over lists.

```
ast> let l = [1,2,3].
ast> let [ h | t ] = l.
ast> h
1
ast> t
[2,3]
ast>
```
Head-Tail Pattern

○ The head-tail pattern can also be used "in reverse" – as a constructor,

- Given an element and a list it will prepend the element to the list

```
[ast> let e = 1.
[ast> let l = [2,3].
[ast> [e|l] is [1,2,3].
true
ast>
```

Pattern Matching with Regular Expressions

- Regular expressions are patterns that can be applied to strings
- e.g., the regex
    "a(b)*"
  matches any string that starts with an a followed by zero or more b's.
- In Asteroid regular expressions are considered patterns and therefore we can write expressions like
    "abbbb" is "a(b)*"
- Asteroid's regex syntax follows Python's regex syntax
 - https://docs.python.org/3/library/re.html

Pattern Matching with Regular Expressions

```
ast> "abbba" is "a(b)*a".
true
ast> "10101" is "(0|1)+".
true
ast> "-1001" is "-?(0|1)+".
true
ast> "1001" is "-?(0|1)+".
true
ast> "1002" is "-?(0|1)+".
false
ast> █
```

Note: (a)+ = a(a)*

Pattern matching with regex

```
1     -- using pattern matching to test whether
2     -- a specific element exists on a list
3
4     load system io.
5     load system type.
6
7     let l = ["turkey", "goose", "chicken", "blue jay"].
8
9     if type @tostring l is ".*blue jay.*" do
10        io @println "the Blue Jay is on the list".
11    else do
12        io @println "Blue Jay was not found".
13    end
```

ln004/list1.ast
